

## **LED UV vs Solvent**

- 1. No VOCs
- 2. No viscosity change during run.
- 3. Print and dries the same regardless of temperature and humidity.
- 4. Prints sharper, essentially dry and set before the next print unit.
- 5. Control dot gain by screens/plate.
- 6. No washup for plugging (ink stable).
- 7. Leave ink in press without washing up at day's end.
- 8. No substrate temperature concerns.
- 9. Max speed is dependent on LED UV power.
- 10. No special electrical hardware required on press.
- 11. Instant on/off no waiting at any time.
- 12. Less quality assurance issues when cured.
- 13. No exhaust of any type no permits needed.

- 1. VOCs
- 2. Constant viscosity monitoring/adjustment.
- 3. Drying changes with temperature and humidity changes.
- 4. Print quality influenced by drying speed and redundant pressure of next print unit.
- 5. Dot gain more variable.
- 6. Need to washup anilox cylinders and plates after stopping.
- 7. Washup necessary at days end.
- 8. Need to adjust dryers to maximize drying without damaging film (which varies with films and ambient conditions).
- 9. Max speed dependent upon temperature and solvent removal level.
- 10. Explosion proof hardware required.
- 11. Need to preheat and then re-heat to operating temperature when stopping for any time (between jobs, make-readies, washup). Dryer is always running.
- 12. Greater potential for ghosting, ink transfer, and migration.
- 13. Natural gas exhaust/ventilation standards required permits needed.
